1. (a) (15%) How many i-nodes will be used if we create a file and create 8 hard links to the file? (b) (15%) How many i-nodes will be used if we create a file and create 7 soft links to the file? (c) (45%) We first create a file ABC, and then create a hard link HL to ABC, a soft link SL to ABC, and another soft link SL2 to HL. Now, we remove ABC (`rm -rf ABC` in Linux). Can we use the hard link HL? Can we use the soft link SL? Can we use the soft link SL2? The reasons have to be provided to support your answers.

Hints: the pictures of a hard link and a soft link

- Answer: (a) 1 i-nodes.
(b) 8 i-nodes.
(c) HL: Yes, it just refers to the same i-node to use the original file.
SL: No, it refers to the path of ABC, and ABC is removed.
SL2: Yes, it refers to the path of HL, and HL still exists.

2. (30%) For file allocation methods, let's make some comparison between contiguous allocation and indexed allocation. What is the disadvantage of contiguous allocation? What is the disadvantage of indexed allocation?

Answer: There could be some external fragmentations if contiguous allocation is used.
It consumes one more block for the index node.
